Background

Cadmium (Cd) and its compounds are well-known environmental carcinogens, but the mechanisms underlying the carcinogenesis are not entirely understood yet. Long non-coding RNAs (lncRNAs) are an important class of pervasive genes involved in a variety of biological functions. They are aberrantly expressed in many types of cancers. In this study, we described lncRNAs profiles in 35th passage of CdCl₂ malignant transformation cells (35th cell) and untransformed human bronchial epithelial cells (16HBE) by microarray.

Methodology/principal findings

With abundant and varied probes accounting 33,045 lncRNAs in our microarray, the number of lncRNAs that expressed at a certain level could be detected is 21409. From the data we found there were 369 lncRNAs were upregulated and 90 lncRNAs were downregulated (≥ 2.0 fold-change, $P < 0.05$) in 35th cells compared with 16HBE cells. Our data showed that upregulated lncRNAs were more common than downregulated ones. ENST0000477387, ENST00000394732, ENST00000485873, ENST00000497538, uc002odz.1, AK023660, NR_023938, BC019085 were evaluated by qPCR in 35th cells compared with 16HBE cells. The eight lncRNAs were aberrantly expressed in 35th cells compared with matched 16HBE cells.

Conclusions/significance

Our study is the first one to determine genome-wide lncRNAs expression patterns in Cadmium-induced malignant transformation by microarray. The results displayed

that clusters of lncRNAs were aberrantly expressed in CdCl₂ malignant transformation cells compared with 16HBE cells, which revealed that lncRNAs differentially expressed in CdCl₂ malignant transformation cells may exert a partial or key role in cadmium-induced cancers. Taken together, this study may provide a viable mechanism for cadmium-induced cancers.
